**Background**

Wake vortices, masses of rotating air trailing an airplane, can have serious consequences for following airplanes. According to the National Transportation Safety Board (NTSB), between 1983 and 1993 there were at least 51 accidents and incidents in the United States that resulted from probable encounters with wake vortices. In these 51 encounters, 27 occupants were killed, 8 occupants were seriously injured, and 40 airplanes were substantially damaged or destroyed.

One of the primary means the FAA uses to reduce the potential of a wake vortex upset is to specify minimum separation distances between airplanes. The relative risk of an upset from a wake vortex encounter is a function of the strength of the vortex generated by the leading airplane, the distance between airplanes, and the roll moment inertia of the trailing airplane. In general, both the strength of a vortex that can be generated by an airplane and an airplane's roll moment inertia are a function of the airplane's weight. Therefore, the FAA specifies minimum separation distances in terms of the
